## CH 3: Differentiation Rules

### 3.5 Implicit Differentiation

1. implicit differentiation works particularly well when the derivative of $y$ must be found, but we cannot solve for $y$ in terms of $x$ in order to find $y^{\prime}$ (see example below)
2. used in finding the derivatives of functions of more than one variables, where the variables depend on each other. That is $y$ is a function of $x$ and chain rule must be used when taking the derivative of $y$ with respect to $x$.
3. for example, if $x^{3}+y^{3}=6 x y$, find $\frac{d y}{d x}$ or $y^{\prime}$ by taking the derivative of both sides of the equation:

$$
\begin{align*}
x^{3}+y^{3} & =6 x y  \tag{1}\\
3 x^{2}+3 y^{2} \frac{d y}{d x} & =6 y+6 x \frac{d y}{d x}  \tag{2}\\
\frac{d y}{d x} & =\frac{6 y-3 x^{2}}{3 y^{2}-6 x}  \tag{3}\\
\frac{d y}{d x} & =\frac{2 y-x^{2}}{y^{2}-2 x} \tag{4}
\end{align*}
$$

4. the above solution can also be written as:

$$
\begin{align*}
x^{3}+y^{3} & =6 x y  \tag{5}\\
3 x^{2}+3 y^{2} y^{\prime} & =6 y+6 x y^{\prime}  \tag{6}\\
y^{\prime} & =\frac{6 y-3 x^{2}}{3 y^{2}-6 x}  \tag{7}\\
y^{\prime} & =\frac{2 y-x^{2}}{y^{2}-2 x} \tag{8}
\end{align*}
$$
